Suppression of Inflammatory Corneal Lymphangiogenesis by Application of Topical Corticosteroids

Deniz Hos, MD; Daniel R. Saban, PhD; Felix Bock, PhD; Birgit Regenfuss, PhD; Jasmine Onderka, MTLA; Sharmila Masli, PhD; Claus Cursiefen, MD

Objectives: To analyze whether topical application of corticosteroids inhibits inflammatory corneal lymphangiogenesis and to study the potential underlying anti-lymphangiogenic mechanisms.

Methods: Inflammatory corneal neovascularization was induced by suture placement, and the corneas were then treated with topical fluorometholone, prednisolone acetate, or dexamethasone sodium phosphate. After 1 week, the corneas were stained with lymphatic vessel endothelial hyaluronan receptor 1 for detection of pathological corneal lymphangiogenesis. The effect of these corticosteroids on macrophage recruitment was assessed via fluorescence-activated cell sorting analysis. The effect of these corticosteroids on proinflammatory cytokine expression by peritoneal exudate cells was tested via real-time polymerase chain reaction. Furthermore, the effect of steroid treatment on the proliferation of lymphatic endothelial cells was assessed via enzyme-linked immunosorbent assay.

Results: Treatment with corticosteroids resulted in a significant reduction of inflammatory corneal lymphangiogenesis. The antilymphangiogenic effect of fluorometholone was significantly weaker than that of prednisolone and dexamethasone. Corneal macrophage recruitment was also significantly inhibited by the application of topical steroids. Treatment of peritoneal exudate cells with corticosteroids led to a significant downregulation of the RNA expression levels of tumor necrosis factor and interleukin 1β. Additionally, proliferation of lymphatic endothelial cells was also inhibited.

Conclusions: Corticosteroids are strong inhibitors of inflammatory corneal lymphangiogenesis, with significant differences between various corticosteroids in terms of their antilymphangiogenic potency. The main mechanism of the antilymphangiogenic effect seems to be through the suppression of macrophage infiltration, pro-inflammatory cytokine expression, and direct inhibition of proliferation of lymphatic endothelial cells.

Clinical Relevance: Steroids block corneal lymphangiogenesis, the main risk factor for immune rejections after corneal transplantation. The different antilymphangiogenic potency of these drugs should be taken into account when using steroids in clinical practice (eg, after keratoplasty).

The healthy cornea is devoid of both blood and lymphatic vessels and actively maintains its avascularity.1-3 However, a variety of inflammatory conditions can lead to a breakdown of this “angiogenic privilege.” This leads to the outgrowth of blood as well as lymphatic vessels from the limbus into the avascular cornea, reducing transparency and visual acuity.4-6 Furthermore, corneal neovascularization is also the most important risk factor for graft rejection after corneal transplantation; in particular, lymphangiogenesis has been shown to be essential in mediating immune reactions after corneal grafting.7-9 By use of the murine model of corneal transplantation, it has recently been shown that inhibition of corneal neovascularization after low- and high-risk corneal transplantation promotes graft survival.10-13 Thus, antiangiogenic therapy is a very reasonable approach for reducing corneal complications secondary to inflammation and also for preventing immune rejections after corneal transplantation.

Recently, several specific angiogenesis inhibitors have been approved by the US Food and Drug Administration for the treatment of pathologic neovascularization in the eye. Ranibizumab (Lucentis; Genentech, South San Francisco, California) and pegaptanib (Macugen; OSI Pharmaceuticals, Farmingdale, New York) were both approved for the treatment of age-related macular degeneration. Bevacizumab (Avastin; Genentech, South San Francisco, California), approved for co-
lorectal cancer and nonsmall cell lung cancer treatment, is also widely used off-label to treat age-related maculopathy, proliferative retinopathies, and neovascular glaucoma. In contrast, no specific angiogenesis inhibitor against neovascularization at the anterior segment of the eye has been approved by the US Food and Drug Administration so far.

However, many older, established drugs also have antiangiogenic properties in addition to their known activities. For instance thalidomide, spironolactone, nonsteroidal anti-inflammatory drugs, and corticosteroids are well-known drugs with known toxicity profiles, and it has been shown that these substances can inhibit angiogenesis in various immune and inflammatory diseases, including those of the eye. Corticosteroids are potent anti-inflammatory drugs widely used for the treatment of macular edema and choroidal and retinal neovascularization. To date, corticosteroid therapy is also the standard anti-inflammatory and antiangiogenic treatment for patients with corneal neovascularization, especially after corneal transplantation. Although it has been established that corticosteroids are able to inhibit corneal hemangiogenesis, little is known about their ability to suppress corneal lymphangiogenesis. Nakao and colleagues showed that systemic application of dexamethasone sodium phosphate was able to inhibit interleukin 1β (IL-1β)–induced corneal hemangiogenesis. However, to our knowledge, it has not been shown whether corticosteroids are also able to inhibit corneal lymphangiogenesis. Therefore, the aims of our study were to assess whether topical application of corticosteroids is able to inhibit inflammatory corneal lymphangiogenesis and to compare the antilymphangiogenic potential of various clinically used corticosteroids (flurorometholone, prednisolone acetate, and dexamethasone). Furthermore, we analyzed the effect of steroids on inflammatory cell recruitment and proinflammatory cytokine expression by macrophages, which are known to be crucial mediators of inflammatory corneal lymphangiogenesis. In addition, we investigated whether steroids are also able to directly suppress the proliferation of lymphatic endothelial cells (LEC).

**METHODS**

**ANIMALS AND ANESTHESIA**

All animal protocols were approved by the local animal care committee and were in accordance to the Association for Research in Vision and Ophthalmology’s Statement for the Use of Animals in Ophthalmology and Vision Research. Mice were anesthetized with an intraperitoneal injection of a combination of 8 mg/kg of ketamine hydrochloride and 0.1 ml/kg of xylazine hydrochloride. All mice were female BALB/c mice, aged 6 to 8 weeks (purchased from Charles River Laboratories, Sulzfeld, Germany).

**SUTURE-INDUCED, INFLAMMATORY CORNEAL NEOVASCULARIZATION ASSAY**

The mouse model of suture-induced inflammatory corneal neovascularization was used as previously described. Prior to corneal neovascularization, each animal was deeply anesthe-

**CORNEAL WHOLE MOUNTS AND MORPHOLOGICAL DETERMINATION OF LYMPHANGIOGENESIS AND HEMANGIOGENESIS**

The excised corneas from the corneal neovascularization assay were rinsed in phosphate-buffered saline (PBS) and fixed in acetone for 30 minutes. After 3 washing steps in PBS and blocking with 2% bovine serum albumin in PBS for 2 hours, the corneas were stained overnight at 4°C with rabbit anti–mouse lymphatic vessel endothelial hyaluronan receptor 1 (1:300; AngioBio Co, Del Mar, California) and rat anti–mouse CD31-FITC (1:50; Accuris Antibodies GmbH, Hiddenhausen, Germany). On day 2, the tissue was washed 3 times; lymphatic vessel endothelial hyaluronan receptor 1 was then detected with a Cy3-conjugated secondary antibody (goat anti–rabbit antibody (1:100; Dianova, Hamburg, Germany). After 3 additional washing steps in PBS, all corneas were moved to Superfrost slides (Menzel-Gläser, Braunschweig, Germany) and covered with Dako fluorescent mounting medium (Hamburg, Germany) and stored at 4°C in the dark.

Stained whole mounts were analyzed with a fluorescence microscope (BX51; Olympus Optical Co, Hamburg, Germany), and digital pictures were taken with a 12-bit monochrome charge-coupled device camera (F-View II; Soft Imaging System, Münster, Germany). Each whole-mount picture was assembled out of 9 pictures taken at 100X magnification. The areas covered with lymphatic and blood vessels were detected with an algorithm established in the image-analyzing program cell-F (Soft Imaging System, Münster, Germany): prior to analysis, gray-value images of the whole-mount pictures were modified by several filters, and vessels were detected by threshold setting, including the bright vessels and excluding the dark background. A detailed explanation of this method was described previously. The mean vascularized area of the control whole mounts was defined as being 100%, and the vascularized areas were then related to this value.

**FLOW CYTOMETRIC ANALYSIS OF INFLAMMATORY CORNEAL CELL RECRUITMENT**

Corneal inflammation was induced by suture placement, and corneas were then treated with topical fluorometholone, pred-
nisolone, dexamethasone (each at a dosage of 1 mg/mL, 3 eye drops daily, 5 µL per drop), or saline solution (control). On days 2 and 5 after suture placement, corneas (3 per group) were harvested and pooled. Single-cell suspensions were prepared from corneal samples using collagenase digestion, as previously described. Brieﬂy, corneal buttons were removed and minced into small fragments, followed by digestion with 2 mg/mL of type IV collagenase (Sigma-Aldrich, St Louis, Missouri) and 0.05 mg/mL of deoxyribonuclease I (Roche, Basel, Switzerland) for 1 hour at 37°C with agitation. The suspension was then triturated through a 10-mL syringe to homogenize the remaining tissue and ﬁltered through a 70-µm cell strainer. Once in single-cell suspension, all samples underwent Fc receptor blockade via incubation with a-Fc receptor (BD Pharmingen, San Diego, California) at 4°C in 0.5% bovine serum (Life Technologies, Carlsbad, California) and 0.05 mg/mL of deoxyribonuclease I (Roche, Basel, Switzerland) for 1 hour at 37°C with agitation. The suspension was then centrifuged at 500 x g and the supernatant was collected and placed on ice. The cell pellet was then washed, resuspended, and cultured at 37°C in RPMI-1640 medium at a density of 4 x 10^5 cells/mL. Cells were incubated for 24 hours with or without 25 nmol/L of dexamethasone. After adhesion, nonadherent cells were removed by washing with culture medium, and adherent cells were then used as macrophages. Cells collected by this method are F4/80-positive and CD11b-negative. Cells were then incubated in RPMI-1640 medium containing 25 nmol/L of fluorometholone, prednisolone, or dexamethasone for 24 hours, followed by RNA isolation. To analyze RNA expression under higher inﬂammatory conditions, 50 ng/mL of tumor necrosis factor (TNF; BioMol GmbH, Hamburg, Germany) was added in some experiments, and cells were then incubated for 24 hours with or without 25 nmol/L of dexamethasone.

RNA ISOLATION AND REAL-TIME POLYMERASE CHAIN REACTION

RNA from cultured peritoneal macrophages was isolated with the RNeasy Micro kit (Qiagen, Hilden, Germany). Complementary DNA was synthesized with random hexamers using reverse transcriptase (SuperScript III; Invitrogen, Darmstadt, Germany) according to the manufacturer’s recommendations. Real-time polymerase chain reaction (PCR) was performed using TaqMan Universal PCR Mastermix and preformulated primers for TNF (assay Mm99999068_m1), IL-1β (assay Mm00434228_m1), and GAPDH (assay Mm99999915_g1). FAM-MGB dye-labeled predesigned primers were used for TNF, IL-1β, and GAPDH (Applied Biosystem, Foster City, California). The results were analyzed by the comparative threshold cycle method and normalized by GAPDH as an internal control.

The relative messenger RNA (mRNA) level in the untreated group was used as the normalized control for the treatment groups. All assays were performed in duplicate; a nontemplate control was included in all of the experiments to evaluate RNA contamination of the reagents. Experiments were conducted twice.

LEC PROLIFERATION ENZYME-LINKED IMMUNOSORBENT ASSAY

The LEC proliferation enzyme-linked immunosorbent assay (ELISA) was used, with slight modiﬁcations, as previously described. Human lymphatic microvascular endothelial cells (Cambrex Bio Science, Walkersville, Maryland) were cultured in EGM2-MV full medium (Cambrex Bio Science) according to the manufacturer’s instructions; EGM2-MV full medium contains endothelial cell growth factors such as vascular endothelial growth factor and basic ﬁbroblast growth factor. For this ELISA, cells were seeded in a 96-well plate in EGM2-MV medium at a density of 4 x 10^4 cells per well. After 6 hours, the medium was replaced with a serum-free medium. 10 µL/mL of 5-bromodeoxyuridine (BrDU; Cell Proliferation ELISA, BrdU, Roche, Penzberg, Germany), and the corticosteroids (25 nmol/L of fluorometholone, prednisolone, or dexamethasone) were added. Cells were ﬁxed and stained after 48 hours according to the manufacturer’s instructions. Colorimetric analysis was performed with the ELISA reader SLT Spectra (SLT Labinstruments Deutschland GmbH, Crailsheim, Germany). The mean extinction of the control wells was deﬁned as being 100%, and extinction of all wells were then related to this value (LEC proliferation ratio).

INHIBITORY EFFECT OF TOPICAL TREATMENT WITH CORTICOSTEROIDS ON CORNEAL LYMPHANGIOGENESIS AND HEMANGIOGENESIS IN VIVO

Treatment with corticosteroids resulted in a signiﬁcant reduction of inﬂammatory corneal lymphangiogenesis in vivo. In comparison with controls, lymphangiogenesis was inhibited by 33% via topical ﬂuorometholone treatment (mean [SD], 67% [19%]; P < .001), by 53% via topical prednisolone treatment (mean [SD], 47% [17%]; P < .001), and by 55% via topical dexamethasone treatment (mean [SD], 45% [13%]; P < .001). The inhibitory effect of ﬂuorometholone was signiﬁcantly weaker than the inhibitory effect of prednisolone or dexamethasone (P < .01). Every tested steroid showed very similar effects on corneal hemangiogenesis: In comparison with controls, blood vessel growth was inhibited by 30% via ﬂuorometholone treatment (mean [SD], 70% [9%]; P < .001), by 50% via topical prednisolone treatment (mean [SD], 50% [12%]; P < .001), and by 57% via topical dexamethasone treatment (mean [SD], 43% [7%]; P < .001). The inhibitory effect of fluorometholone was again signiﬁcantly weaker than the inhibitory effect of prednisolone or dexamethasone (P < .01) (Figure 1).
INHIBITORY EFFECT OF TOPICAL TREATMENT WITH CORTICOSTEROIDS ON INFLAMMATORY CELL RECRUITMENT IN VIVO

To examine the effect of topical corticosteroid treatment on suture-induced macrophage infiltration, we quantified the number of F4/80+CD11b+ cells using flow cytometry. Fluorescence-activated cell sorting analysis showed that topical treatment with corticosteroids resulted in a significant reduction of inflammatory cell recruitment in vivo. Although, in control corneas, the percentage of F4/80+CD11b+ macrophages per cornea was 23.58% at 2 days after corneal suture placement and 27.14% at 5 days after corneal suture placement, treatment with fluorometholone reduced the amount of F4/80+CD11b+ cells to 2.07% at day 2 and 13.57% at day 5. Treatment with prednisolone reduced the amount of F4/80+CD11b+ cells to 4.51% at day 2 and 10.44% at day 5, and treatment with dexamethasone reduced the amount of F4/80+CD11b+ cells to 1.88% at day 2 and 11.86% at day 5. All of the steroids used led to a stronger inhibitory effect on macrophage recruitment on day 2 than on day 5 (Figure 2).

SUPPRESSIVE EFFECT OF CORTICOSTEROIDS ON PROINFLAMMATORY CYTOKINE EXPRESSION BY MACROPHAGES IN VITRO

Peritoneal exudate cells were incubated with 25-nmol/L fluorometholone, prednisolone, or dexamethasone for 24 hours, and mRNA expression levels of the proinflammatory cytokines TNF and IL-1β were then measured via real-time PCR. In vitro treatment of resting peritoneal exudate cells with corticosteroids led to a significant inhibition of mRNA expression levels of TNF and IL-1β. Fluorometholone treatment inhibited mRNA expression levels by 83% (TNF) and 68% (IL-1β), whereas prednisolone treatment suppressed mRNA expression levels by 79% (TNF) and 50% (IL-1β). Dexamethasone was the strongest inhibitor of proinflammatory cytokine expression: TNF expression was reduced by 88%, and IL-1β expression by 73%. With respect to TNF expression levels, there were no significant differences detectable between fluorometholone treatment and prednisolone treatment (P > .05) or between fluorometholone treatment and dexamethasone treatment (P > .05). However, treatment with...
dexamethasone showed a statistically stronger inhibition of TNF mRNA expression than did treatment with prednisolone ($P < .05$). The assessment of IL-1β mRNA levels revealed that both fluorometholone and dexamethasone had a stronger inhibitory effect on IL-1β expression than did prednisolone ($P < .01$), with the effect of fluorometholone and dexamethasone being comparable ($P > .05$).

To analyze whether steroids can also inhibit TNF and IL-1β expression under higher inflammatory conditions, peritoneal exudate cells were incubated with 50 ng/mL of TNF. The addition of this inflammatory stimulus led to a strong upregulation of proinflammatory cytokine expression (a 4.6-fold increase in TNF expression and a 4.4-fold increase in IL-1β expression). However, further treatment with dexamethasone could still suppress proinflammatory cytokine expression, even under this inflammatory stimulation (a 0.3-fold decrease TNF expression and a 0.4-fold decrease IL-1β expression) (Figure 3).

**SUPPRESSIVE EFFECT OF CORTICOSTEROIDS ON LEC PROLIFERATION IN VITRO**

To assess whether corticosteroids have a direct effect on LECs as well, we studied their effect on LEC proliferation in vitro. Treatment with corticosteroids (dose, 25 nmol/L) significantly suppressed the proliferation of LECs. Compared with controls, application of fluorometholone resulted in an inhibition of LEC proliferation by 42% ($P < .001$), application of prednisolone resulted in an inhibition of LEC proliferation by 30% ($P < .001$), and application of dexamethasone resulted in an inhibition of LEC proliferation by 51% ($P < .001$). Between the analyzed steroids, prednisolone had the weakest effect on LEC proliferation (prednisolone vs fluorometholone [$P < .01$]; prednisolone vs dexamethasone [$P < .001$]). Dexamethasone was the strongest inhibitor of LEC proliferation (dexamethasone vs fluorometholone; $P < .05$) (Figure 4).

![Figure 2](http://archopht.jamanetwork.com/pdfaccess.ashx?url=/data/journals/ophth/10237/)

**Figure 2.** Inhibitory effect of topical treatment with corticosteroids on inflammatory cell recruitment in vivo. Fluorescence-activated cell sorting analysis of F4/80+/CD11b+ cells obtained from corneas after suture placement. Cell recruitment was strongly inhibited by topical fluorometholone, prednisolone acetate, or dexamethasone sodium phosphate. All of the steroids used led to a stronger inhibition of cell recruitment on day 2 than on day 5. FITC indicates fluorescein isothiocyanate; and PE, phycoerythrin.

The experiments performed in our study demonstrate the following: (1) Corticosteroids are potent inhibitors of inflammation-induced lymphangiogenesis and hemangiogenesis in vivo. (2) Significant differences exist between different corticosteroids with respect to their antilymphangiogenic and antihemangiogenic properties. In general, the stronger the anti-inflammatory effect, the stronger the in vivo antilymphangiogenic and antihemangiogenic effect. This fits well with the known close interrelation between inflammation and angiogenesis. (3) Corticosteroids strongly block inflammatory cell recruitment into the inflamed cornea. It has already been shown that systemic application of dexamethasone was able to inhibit the recruitment of CD11b single positive cells after IL-1β pellet implantation. We analyzed the effect of topical steroid treatment on F4/80+CD11b+ double-positive cells after corneal suture placement in order to primarily focus on the role of macrophages, because various leukocyte populations (eg, granulocytes and natural killer cells) also express CD11b, whereas F4/80 seems to be mainly expressed by macrophages. Furthermore, compared with pellet implantation, the suture-induced neovascularization model used in our study is known to induce a strong inflammatory response. The inhibition of F4/80+CD11b+ macrophage infiltration by steroids af-
ter suture placement allowed us to conclude that, even under these very high inflammatory conditions, corticosteroids strongly block macrophage recruitment after topical application.

(4) In vitro, corticosteroids significantly inhibit proinflammatory cytokine expression by macrophages. It is well established that both TNF and IL-1β (IL-1β) mediate corneal neovascularization.37,38 In particular, TNF expressed by macrophages is known to be an important factor that induces angiogenesis.39 We could show that steroids are able to suppress proinflammatory cytokine expression, both under resting and inflammatory conditions. Therefore, blockade of macrophage-derived expression of TNF and IL-1β levels by steroids likely contributes to the strong antilymphangiogenic effect of these substances.

(5) Moreover, corticosteroids also suppress LEC proliferation, indicating that the antilymphangiogenic effect of these substances is due not only to anti-inflammatory properties but also partly to direct anti-proliferative properties.

Flurometholone, the weakest of the 3 anti-inflammatory corticosteroids tested, had the least effect on corneal lymphangiogenesis in vivo; however, it did have a stronger inhibitory effect than did prednisolone in vitro. Prednisolone had significantly stronger inhibitory effects in vivo; however, it had the weakest inhibitory effect in vitro. Therefore, additional properties (eg, tissue and cell penetration and substance half-life) also seem to be responsible for the overall inhibitory effect in vivo. Indeed, it has been shown that fluorometholone has a relatively short half-life and rapid metabolism.40 Dexamethasone was the most potent inhibitor in almost all conducted experiments. The different antilymphangiogenic potentials of these 3 corticosteroids should be taken into account when using them in clinical practice (eg, after keratoplasty). Also, however, the risk of adverse effects seems to decrease in parallel with the anti-inflammatory potency of the particular steroid. For example, it has been established that fluorometholone increases intraocular pressure less frequently than does prednisolone or dexamethasone.

The benefit of a steroid with higher anti-inflammatory and, as shown in our study, also higher
antiangiogenic properties surely has to be weighed against its increasing risk of adverse effects in patients. A plethora of clinical indications exist for antiangiogenic treatment of the cornea (eg, to stop sight-threatening neovascularization after inflammation or to improve graft survival after corneal transplantation).4,41-45 To date, steroid therapy is the standard anti-inflammatory and antiangiogenic treatment for patients with corneal neovascularization, especially after corneal transplantation.15 Furthermore, it is widely accepted that topical steroid treatment protects against immunologic graft rejection after corneal transplantation.12,14 This protection may largely be attributable to the fact that corticosteroids are very potent anti-inflammatory substances. The fact that these substances are also able to inhibit lymphangiogenesis, as shown in our study, and that lymphangiogenesis has been shown to be an important risk factor regarding graft rejection after corneal transplantation17 may lead one to conclude that both the anti-inflammatory effects and the antilymphangiogenic properties of these substances can result in a better outcome for patients after corneal transplantation.

However, the use of steroid therapy in the management of eye diseases remains controversial because of the adverse effects associated with this type of therapy.23,46 Alternative therapeutic approaches are necessary; for example, specifically blocking angiogenesis by targeting vascular endothelial growth factor appears to be a very reasonable and promising approach with less adverse effects.18,47 In fact, initial successful results were obtained using specific antiangiogenic drugs at the cornea (eg, bevacizumab eye drops and GS–101 antisense oligonucleotide eye drops).48,49

Call for Papers

The editorial staff of Archives of Ophthalmology is pleased to announce a new section in the journal. In 2008 the Surgeon’s Corner was phased in as a regular feature in Archives and focuses on surgical aspects of ophthalmology. The goal for this section is to provide readers with current information on surgical techniques, devices and outcomes and perioperative management. Consideration for inclusion in Surgeon’s Corner will be given to manuscripts addressing broadly applicable techniques using reasonably accessible technology. Preference for publication will be given to concise manuscripts whose results and conclusions are adequately supported by data and rigorous statistical analysis. Manuscripts submitted along with high-quality videos for online publication in Archives of Ophthalmology (http://www.archophthalmol.com) are strongly encouraged, and the accompanying video will be considered during the review process. Papers should fit into existing categories for Clinical Trials, Clinical Science, New Instruments, Surgical Techniques, or Research Letters as described in Instructions for Authors. A desire to be considered for this new section should be indicated by the authors at the time of manuscript submission.
